# PSTAT131 HW4

# Tao Wang

## 2022-05-02

Load the data from  $\mathtt{data/titanic.csv}$  into R and familiarize yourself with the variables it contains using the codebook  $\mathtt{(data/titanic\_codebook.txt)}$ .

Notice that survived and pclass should be changed to factors. When changing survived to a factor, you may want to reorder the factor so that "Yes" is the first level.

Make sure you load the tidyverse and tidymodels!

Remember that you'll need to set a seed at the beginning of the document to reproduce your results.

Create a recipe for this dataset **identical** to the recipe you used in Homework 3.

```
# prepare

## [1] "Yes" "No"

#### Question 1

Split the data, stratifying on the outcome variable, survived. You should choose the proportions to split the data into. Verify that the training and testing data sets have the appropriate number of observations.

- ## [1] 179 12
  - Each dataset has approximately the right number of observations;
  - For the training data set, 712 is almost exactly 80% of the full data set, which contains 891 observations. So, the training data set has approximately the right number of observations.
  - For the testing data set, 179 is almost exactly 20% of the full data set, which contains 891 observations. So, the testing data set has approximately the right number of observations.

## Question 2

Fold the **training** data. Use k-fold cross-validation, with k = 10.

```
titanic_folds <- vfold_cv(titanic_train, v = 10)
titanic_folds</pre>
```

```
## # 10-fold cross-validation
## # A tibble: 10 x 2
##
      splits
                       id
##
      t>
                       <chr>>
##
   1 <split [640/72] > Fold01
##
   2 <split [640/72] > Fold02
## 3 <split [641/71] > Fold03
## 4 <split [641/71] > Fold04
## 5 <split [641/71] > Fold05
## 6 <split [641/71] > Fold06
## 7 <split [641/71] > Fold07
## 8 <split [641/71] > Fold08
## 9 <split [641/71] > Fold09
## 10 <split [641/71] > Fold10
```

## Question 3

In your own words, explain what we are doing in Question 2. What is k-fold cross-validation? Why should we use it, rather than simply fitting and testing models on the entire training set? If we **did** use the entire training set, what resampling method would that be?

## Answer

• 1. In Qurstion2, we are randomly dividing the training data into 10 groups (or folds) of (roughly) equal sizes.

- 2. According to the textbook, k-fold cross-validation is an approach that involves randomly dividing the set of observations into k groups, or folds, of approximately equal size. The first fold is treated as a validation set, and the method is fit on the remaining k-1 folds. The mean squared error,  $MSE_1$ , is then computed on the observations in the held-out fold. This procedure is repeated k times; each time, a different group of observations is treated as a validation set. This process results in k estimates of the test error,  $MSE_1$ ,  $MSE_2$ ,..., $MSE_k$ . The k-fold CV estimate is computed by averaging these value. (Page 203)
- 3. According to the TA, if we simply fit and test models on the entire training set, it may cause overfitting. To avoid causing overfitting, we should use k-fold cross-validation.
- 4. Bootstrap

#### Question 4

Set up workflows for 3 models:

- 1. A logistic regression with the glm engine;
- 2. A linear discriminant analysis with the MASS engine;
- 3. A quadratic discriminant analysis with the MASS engine.

How many models, total, across all folds, will you be fitting to the data? To answer, think about how many folds there are, and how many models you'll fit to each fold.

```
# Create a recipe for this dataset **identical** to the recipe you used in Homework 3.
titanic_recipe <-recipe(survived ~ pclass + sex + age + sib_sp +parch + fare,
                              data = titanic_train) %>%
step impute linear(age) %>%
step_dummy(all_nominal_predictors()) %>%
step_interact(terms = ~ starts_with('sex'):fare)%>%
step_interact(terms = ~ age:fare)
# 1. A logistic regression with the `glm` engine;
log_reg <- logistic_reg() %>%
  set_engine("glm") %>%
  set_mode("classification")
log wkflow <- workflow() %>%
  add_model(log_reg) %>%
  add_recipe(titanic_recipe)
# 2. A linear discriminant analysis with the `MASS` engine;
lda_mod <- discrim_linear() %>%
  set_mode("classification") %>%
  set_engine("MASS")
lda_wkflow <- workflow() %>%
  add_model(lda_mod) %>%
  add_recipe(titanic_recipe)
# 3. A quadratic discriminant analysis with the `MASS` engine.
qda_mod <- discrim_quad() %>%
  set_mode("classification") %>%
  set_engine("MASS")
qda_wkflow <- workflow() %>%
  add_model(qda_mod) %>%
  add recipe(titanic recipe)
```

- How many models, total, across all folds, will you be fitting to the data?
- Answer: Since we have 3 different types of models, and for each type of model, we have 10 folds. Then, we will fit 30 models in total to the data.

#### Question 5

Fit each of the models created in Question 4 to the folded data.

**IMPORTANT:** Some models may take a while to run – anywhere from 3 to 10 minutes. You should NOT re-run these models each time you knit. Instead, run them once, using an R script, and store your results; look into the use of loading and saving. You should still include the code to run them when you knit, but set **eval = FALSE** in the code chunks.

- how can we fit our model to the floded data?
- do we need to use keep pred <- control resamples (save pred = TRUE, save workflow = TRUE)

```
log_fit <- fit_resamples(log_wkflow, titanic_folds)
lda_fit <- fit_resamples(lda_wkflow, titanic_folds)
qda_fit <- fit_resamples(qda_wkflow, titanic_folds)</pre>
```

## Question 6

Use collect\_metrics() to print the mean and standard errors of the performance metric accuracy across all folds for each of the 3 models.

Decide which of the 3 fitted models has performed the best. Explain why. (Note: You should consider both the mean accuracy and its standard error.)

```
collect_metrics(log_fit)
```

## 1 accuracy binary

## 2 roc\_auc binary

0.785

0.845

```
## # A tibble: 2 x 6
##
     .metric .estimator mean

```

10 0.0180 Preprocessor1\_Model1

10 0.0223 Preprocessor1\_Model1

Decide which of the 3 fitted models has performed the best. Explain why. (Note: You should consider both the mean accuracy and its standard error.)

- Since we should consider both the mean accuracy and its standard error, then it will be reasonable for us to consider about the 95 % confidence interval for each models. According to the TA, it is good for us to treat the mean accuracy (we got in this question) as the sample mean, and we can calculate the 95% confidence interval for the population mean
- For logistic model, by what we learned in PSTAT 120B, we know that 95% confidence interval is (0.806 1.96 \* 0.0195, 0.806 + 1.96 \* 0.0195) = (0.768, 0.844)
- For LDA model, by what we learned in PSTAT 120B, we know that 95% confidence interval is (0.798-1.96\*0.0193, 0.798+1.96\*0.0193) = (0.760, 0.836)
- For QDA model, by what we learned in PSTAT 120B, we know that 95% confidence interval is (0.785 1.96 \* 0.0180, 0.785 + 1.96 \* 0.0180) = (0.750, 0.820)
- By comparing these three models, we can find that the logistic regression model have both highest lower bound and highest upper bound of the confidence interval. So, we can conclude that the logistic regression model has performed the best.

#### Question 7

Now that you've chosen a model, fit your chosen model to the entire training dataset (not to the folds).

```
lm_fit <- fit(log_wkflow, titanic_train)</pre>
```

# Question 8

Finally, with your fitted model, use predict(), bind\_cols(), and accuracy() to assess your model's performance on the testing data!

Compare your model's testing accuracy to its average accuracy across folds. Describe what you see.

```
# 1. use `predict()`, `bind_cols()`, and `accuracy()` to assess your model's performance
# on the testing data!
log_acc <- predict(lm_fit, new_data = titanic_test, type = "class") %>%
  bind_cols(titanic_test %>% select(survived)) %>%
  accuracy(truth = survived, estimate = .pred class)
log_acc # it tells us the model's testing accuracy
## # A tibble: 1 x 3
##
     .metric .estimator .estimate
     <chr>>
              <chr>
                             <dbl>
## 1 accuracy binary
                             0.782
# Recall, the model's average accuracy across folds
collect_metrics(log_fit)
## # A tibble: 2 x 6
                                   n std_err .config
##
     .metric .estimator mean
##
     <chr>>
              <chr>
                         <dbl> <int>
                                       <dbl> <chr>
## 1 accuracy binary
                         0.806
                                  10 0.0195 Preprocessor1_Model1
## 2 roc_auc binary
                                  10 0.0188 Preprocessor1_Model1
                         0.850
```

- My model's testing accuracy is 0.782
- My model's average accuracy across folds is 0.806
- We can see that the model's testing accuracy is less than the model's average accuracy across folds.
